**DYNAMIC ASSIGNMENT OF TRAFFIC CLASSES TO A PRIORITY QUEUE IN A PACKET FORWARDING DEVICE**

**CROSS-REFERENCE TO RELATED APPLICATION**

[0001] The present application claims priority under 35 U.S.C. §119(e) from provisional application Ser. No. 60/226, 787, and is related to U.S. patent application Ser. No. 09/227, 389, both applications being incorporated herein by reference.

**FIELD OF THE INVENTION**

[0002] The present invention relates to the field of telecommunications, and more particularly to dynamic assignment of traffic classes to queues having different priority levels.

**BACKGROUND OF THE INVENTION**

[0003] The flow of packets through packet-switched networks is controlled by switches and routers that forward packets based on destination information included in the packets themselves. A typical switch or router includes a number of input/output (I/O) modules connected to a switching fabric, such as a crossbar or shared memory switch. In some switches and routers, the switching fabric is operated at a higher frequency than the transmission frequency of the I/O modules so that the switching fabric may deliver packets to an I/O module faster than the I/O module can output them to the network transmission medium. In these devices, packets are usually queued in the I/O module to await transmission.

[0004] One problem that may occur when packets are queued in the I/O module or elsewhere in a switch or router is that the queuing delay per packet varies depending on the amount of traffic being handled by the switch. Variable queuing delays tend to degrade data streams produced by real-time sampling (e.g., audio and video) because the original time delays between successive packets in the stream convey the sampling interval and are therefore needed to faithfully reproduce the source information. Another problem that results from queuing packets in a switch or router is that data from a relatively important source, such as a shared server, may be impeded by data from less important sources, resulting in bottlenecks.

**SUMMARY OF THE INVENTION**

[0005] A method and apparatus for dynamic assignment of classes of traffic to a priority queue are disclosed. Bandwidth consumption by one or more types of packet traffic received in a packet forwarding device is monitored. The queue assignment of at least one type of packet traffic is automatically changed from a queue having a first priority to a queue having a second priority if the bandwidth consumption exceeds the threshold.

[0006] Other features and advantages of the invention will be apparent from the accompanying drawings and from the detailed description that follows below.

**BRIEF DESCRIPTION OF THE DRAWINGS**

[0007] The present invention is illustrated by way of example and not limitation in the figures of the accompanying drawings in which like references indicate similar elements and in which:

[0008] FIG. 1 illustrates a packet forwarding device that can be used to implement embodiments of the present invention;

[0009] FIG. 2A illustrates queue fill logic implemented by a queue manager in a quad interface device, and FIG. 2B illustrates queue drain logic according to one embodiment;

[0010] FIG. 3 illustrates the flow of a packet within the switch of FIG. 1;

[0011] FIG. 4 illustrates storage of an entry in an address resolution table managed by an address resolution unit;

[0012] FIG. 5 is a diagram of the software architecture of the switch of FIG. 1 according to one embodiment; and

[0013] FIG. 6 illustrates an example of dynamic assignment of traffic classes to a priority queue.

**DETAILED DESCRIPTION OF THE PRESENTLY PREFERRED EXEMPLARY EMBODIMENTS**

[0014] A packet forwarding device in which selected classes of network traffic may be dynamically assigned for priority queuing is disclosed. In one embodiment, the packet forwarding device includes a Java virtual machine for executing user-coded Java applets received from a network management server (NMS). A Java-to-native interface (JNI) is provided to allow the Java applets to obtain error information and traffic statistics from the device hardware and to allow the Java applets to write configuration information to the device hardware, including information that indicates which classes of traffic should be queued in priority queues. The Java applets implement user-specified traffic management policies based on real-time evaluation of the error information and traffic statistics to provide dynamic control of the priority queuing assignments. These and other aspects and advantages of the present invention are described below.

[0015] It should be noted that the use of the Java language is not a requirement for practicing the present invention. Although Java provides a number of advantages when used to implement the present invention, e.g., dynamic on-demand use, other programming languages such as C may be used in its place.

[0016] FIG. 1 illustrates a packet forwarding device 17 that can be used to implement embodiments of the present invention. For the purposes of the present description, the packet forwarding device 17 is assumed to be a switch that switches packets between ingress and egress ports based on media access control (MAC) addresses within the packets. In an alternate embodiment, the packet forwarding device 17 may be a router that routes packets according to destination internet protocol (IP) addresses or a routing switch that performs both MAC address switching and IP address routing. The techniques and structures disclosed herein are applicable generally to a device that forwards packets in a packet switching network. Also, the term packet is used broadly herein to refer to a fixed-length cell, a variable length frame or any other information structure that is self-contained as to its destination address.

[0017] The switch 17 includes a switching fabric 12 coupled to a plurality of I/O units (only I/O units 1 and 16 are depicted) and to a processing unit 10. The processing unit includes at least a processor 31 (which may be a microprocessor, digital signal processor or microcontroller) coupled to a memory 32 via a bus 33. In one embodiment, each I/O unit 1, 16 includes four physical ports P1-P4 coupled to a quad media access controller (QMAC) 14A, 14B via respective transceiver interface units 21A-24A, 21B-24B. Each I/O unit

**1, 16** also includes a quad interface device (QID) **16A, 16B**, an address resolution unit (ARU) **15A, 15B** and a memory **18A, 18B**, interconnected as shown in FIG. 1. Preferably, the switch **17** is modular with at least the I/O units **1, 16** being implemented on port cards (not shown) that can be installed in a backplane (not shown) of the switch **17**. In one implementation, each port card includes a given number of I/O units and therefore supports a corresponding number of physical ports. The switch backplane includes slots for a given number of port cards, so that the switch **17** can be scaled according to customer needs to support a number of physical ports as controlled by the number of port cards. In alternate embodiments, each I/O unit **1, 16** may support more or fewer physical ports each port card may support more or fewer I/O units **1, 16** and the switch **17** may support more or fewer port cards. For example, the I/O unit **1** shown in FIG. 1 may be used to support 0baseT transmission lines (i.e., 10 Mbps (mega-bit per second), twisted-pair) or 00baseF transmission lines (100 Mbps, fiber optic), while a different I/O unit (not shown) may be used to support a 1000baseF transmission line (1000 Mbps, fiber optic). Nothing disclosed herein should be construed as limiting embodiments of the present invention to use with a particular transmission medium, I/O unit, port card or chassis configuration.

[0018] Still referring to FIG. 1, when a packet **25** is received on physical port **P1**, it is supplied to the corresponding physical transceiver **21A** which performs any necessary signal conditioning (e.g. optical to electrical signal conversion) and then forwards the packet **25** to the QMAC **14A**. The QMAC **14A** buffers packets received from the physical transceivers **21A-24A** as necessary, forwarding one packet at a time to the QID **16A**. Receive logic within the QID **16A** notifies the ARU **15A** that the packet **25** has been received. The ARU computes a table index based on the destination MAC address within the packet **25** and uses the index to identify an entry in a forwarding table that corresponds to the destination MAC address. In packet forwarding devices that operate on different protocol layers of the packet (e.g., routers), a forwarding table may be indexed based on other destination information contained within the packet.

[0019] According to one embodiment, the forwarding table entry identified based on the destination MAC address indicates the switch egress port to which the packet **25** is destined and also whether the packet is part of a MAC-address based virtual local area network (VLAN), or a port-based VLAN. (As an aide a VLAN is a logical grouping of MAC addresses (a MAC-address-based VLAN) or a logical grouping of physical ports (a port-based VLAN).) The forwarding table entry further indicates whether the packet **25** is to be queued in a priority queue in the I/O unit that contains the destination port. As discussed below, priority queuing may be specified based on a number of conditions, including, but not limited to, whether the packet is part of a particular IP flow, or whether the packet is destined for a particular port, VLAN or MAC address.

[0020] According to one embodiment, the QID **16A, 16B** segments the packet **25** into a plurality of fixed-length cells **26** for transmission through the switching fabric **12**. Each cell includes a header **28** that identifies it as a constituent of the packet **25** and that identifies the destination port for the cell (and therefore for the packet **25**). The header **28** of each cell also includes a bit **29** indicating whether the cell is the beginning cell of a packet and also a bit **30** indicating whether the

packet **25** to which the cell belongs is to be queued in a priority queue or a best effort queue on the destined I/O unit.

[0021] The switching fabric **12** forwards each cell to the I/O unit indicated by the cell header **28**. In the exemplary data flow shown in FIG. 1, the constituent cells **26** of the packet **25** are assumed to be forwarded to I/O unit **16** where they are delivered to transmit logic within the QID **16B**. The transmit logic in the QID **16B** includes a queue manager (not shown) that maintains a priority queue and a best effort queue in the memory **18B**. In one embodiment, the memory **18B** is resolved into a pool of buffers, each large enough to hold a complete packet. When the beginning cell of the packet **25** is delivered to the QID **16B**, the queue manager obtains a buffer from the pool and appends the buffer to either the priority queue or the best effort queue according to whether the priority bit **30** is set in the beginning cell. In one embodiment, the priority queue and the best effort queue are each implemented by a linked list, with the queue manager maintaining respective pointers to the head and tail of each linked list. Entries are added to the tail of the queue list by advancing the tail pointer to point to a newly allocated buffer that has been appended to the linked list, and entries are popped off the head of the queue by advancing the head pointer to point to the next buffer in the linked list and returning the spent buffer to the pool.

[0022] After a buffer is appended to either the priority queue or the best effort queue, the beginning cell and subsequent cells are used to reassemble the packet **25** within the buffer. Eventually the packet **25** is popped off the head of the queue and delivered to an egress port via the QMAC **14B** and the physical transceiver (e.g., **23B**) in an egress operation. This is shown by way of example in FIG. 1 by the egress of packet **25** from physical port **P3** of I/O unit **16**.

[0023] FIG. 2A illustrates queue fill logic implemented by the queue manager in the QID. Starting at block **51**, a cell is received in the QID from the switching fabric. The beginning cell bit in the cell header is inspected at decision block **53** to determine if the cell is the beginning cell of a packet. If so, the priority bit in the cell header is inspected at decision block **55** to determine whether to allocate an entry in the priority queue or the best effort queue for packet reassembly. If the priority bit is set, an entry in the priority queue is allocated at block **57** and the priority queue entry is associated with the portion of the cell header that identifies the cell as a constituent of a particular packet at block **59**. If the priority bit in the cell header is not set, then an entry in the best effort queue is allocated at block **61** and the best effort queue entry is associated with the portion of the cell header that identifies the cell as a constituent of a particular packet at block **63**.

[0024] Returning to decision block **53**, if the beginning cell bit in the cell header is not set, then the queue entry associated with the cell header is identified at block **65**. The association between the cell header and the queue entry identified at block **65** was established earlier in either block **59** or block **63**. Also, identification of the queue entry in block **65** may include inspection of the priority bit in the cell to narrow the identification effort to either the priority queue or the best effort queue. In block **67**, the cell is combined with the preceding cell in the queue entry in a packet reassembly operation. If the reassembly operation in block **67** results in a completed packet (decision block **69**), then the packet is marked as ready for transmission in block **71**. In one embodiment, the packet is marked by setting a flag associated with the queue entry in

which the packet has been reassembled. Other techniques for indicating that a packet is ready for transmission may be used in alternate embodiments.

**[0025]** FIG. 2B illustrates queue drain logic according to one embodiment. At decision block 75, the entry at the head of the priority queue is inspected to determine if it contains a packet ready for transmission. If so, the packet is transmitted at block 77 and the corresponding priority queue entry is popped off the head, of the priority queue and deallocated at block 79. If a ready packet is not present at the head of the priority queue, then the entry at the head of the best effort queue is inspected at decision block 81. If a packet is ready at the head of the best effort queue, it is transmitted at block 83 and the corresponding best effort queue entry is popped off the head of the best effort queue and deallocated in block 85. Note that, in the embodiment illustrated in FIG. 2B, packets are drained from the best effort queue only after the priority queue has been emptied. In alternate embodiments, a timer, counter or similar logic element may be used to ensure that the best effort queue 105 is serviced at least every so often or at least after every N number of packets are transmitted from the priority queue, thereby ensuring at least a threshold level of service to best effort queue.

**[0026]** FIG. 3 illustrates the flow of a packet within the switch 17 of FIG. 1. A packet is received in the switch at block 91 and used to identify an entry in a forwarding table called the address resolution (AR) table at block 93. At decision block 95, a priority bit in the AR table entry is inspected to determine whether the packet belongs to a class of traffic that has been selected for priority queuing. If the priority bit is set, the packet is segmented into cells having respective priority bits set in their headers in block 97. If the priority bit is not set, the packet is segmented into cells having respective priority bits cleared their cell headers in block 99. The constituent cells of each packet are forwarded to an egress I/O unit by the switching fabric. In the egress I/O unit, the priority bit of each cell is inspected (decision block 101) and used to direct the cell to an entry in either the priority queue 103 or the best effort queue 105 where it is combined with other cells to reassemble the packet.

**[0027]** FIG. 4 illustrates storage of an entry in the address resolution (AR) table managed by the ARU. In one embodiment, the AR table is maintained in a high speed static random access memory (SRAM) coupled to the ARU. Alternatively, the AR table may be included in a memory within an application-specific integrated circuit (ASIC) that includes the ARU. Generally, the ARU stores an entry in the AR table in response to packet forwarding information from the processing unit. The processing unit supplies packet forwarding information to be stored in each AR table in the switch whenever a new association between a destination address and a switch egress port is learned. In one embodiment, an address-to-port association is learned by transmitting a packet that has an unknown egress port assignment on each of the egress ports of the switch and associating the destination address of the packet with the egress port at which an acknowledgment is received. Upon learning the association between the egress port and the destination address, the processing unit issues forwarding information that includes, for example, an identifier of the newly associated egress port, the destination MAC address, an identifier of the VLAN associated with the MAC address (if any), an identifier of the VLAN associated with the egress port (if any), the destination IP address the destination IP port (e.g., transmission control protocol (TCP),

universal device protocol (UDP) or other IP port) and the IP protocol (e.g., HTTP, FTP or other IP protocol). The source IP address, source IP port and source IP protocol may also be supplied to fully identify an end-to-end IP flow.

**[0028]** Referring to FIG. 4, forwarding information 110 is received from the processing unit at block 115. At block 117, the ARU stores the forwarding information in an AR table entry. At decision block 119, the physical egress port identifier stored in the AR table entry is compared against priority configuration information to determine if packets destined for the egress port have been selected for priority egress queuing. If so, the priority bit is set in the AR table entry in block 127. Thereafter, incoming packets that index the newly stored table entry will be queued in the priority queue to await transmission. If packets destined for the egress port have not been selected for priority queuing, then at decision block 121 the MAC address stored in the AR table entry is compared against the priority configuration information to determine if packets destined for the MAC address have been selected for priority egress queuing. If so, the priority bit is set in the AR table entry in block 127. If packets destined for the MAC address have not been selected for priority egress queuing, then at decision block 123 the VLAN identifier stored in the AR table entry (if present) is compared against the priority configuration information to determine if packets destined for the VLAN have been selected for priority egress queuing. If so, the priority bit is set in the AR table entry in block 127. If packets destined for the VLAN have not been selected for priority egress queuing, then at block 125 the IP flow identified by the IP address, IP port and IP protocol in the AR table is compared against the priority configuration information to determine if packets that form part of the IP flow have been selected for priority egress queuing. If so, the priority bit is set in the AR table entry, otherwise the priority bit is not set. Yet other criteria may be considered in assigning priority queuing in alternate embodiments. For example, priority queuing may be specified for a particular IP protocol (e.g. FTP, HTTP). Also, the ingress port, source MAC address or source VLAN of a packet may also be used to determine whether to queue the packet in the priority egress packet. More specifically, in one embodiment, priority or best effort queuing of unicast traffic is determined based on destination parameters (e.g., egress port, destination MAC address or destination IP address), while priority or best effort queuing of multicast traffic is determined based on source parameters (e.g., ingress port source MAC address or source IP address).

**[0029]** FIG. 5 is a diagram of the software architecture of the switch 17 of FIG. 1 according to one embodiment. An operating system 143 and device drivers 145 are provided to interface with the device hardware 141. For example, device drivers are provided to write configuration information and AR storage entries to the ARUs in respective I/O units. Also, the operating system 143 performs memory management functions and other system services in response to requests from higher level software. Generally, the device drivers 145 extend the services provided by the operating system and are invoked in response to requests for operating system service that involve device-specific operations.

**[0030]** The device management code 147 is executed by the processing unit (e.g., element 10 of FIG. 1) to perform system level functions, including management of forwarding entries in the distributed AR tables and management of forwarding entries in a master forwarding table maintained in the memory of the processing unit. The device management code

**147** also includes routines for invoking device driver services, for example, to query the ARU for traffic statistics and error information, or to write updated configuration information to the ARUs, including priority queuing information. Further, the device management code **147** includes routines for writing updated configuration information to the ARUs, as discussed below in reference to FIG. 6. In one implementation, the device management code **147** is native code, meaning that the device management code **147** is a compiled set of instructions that can be executed directly by a processor in the processing unit to carry out the device management functions.

**[0031]** In one embodiment, the device management code **147** supports the operation of a Java client **160** that includes a number of Java applets, including a monitor applet **157**, a policy enforcement applet **159** and configuration applet **161**. A Java applet is an instantiation of a Java class that includes one or more methods for self initialization (e.g., a constructor method called "Applet( )"), and one or more methods for communicating with a controlling application. Typically the controlling application for a Java applet is a web browser executed on a general purpose computer. In the software architecture shown in FIG. 5, however, a Java application called Data Communication Interface (DCI) **153** is the controlling application for the monitor, policy enforcement and configuration applets **157**, **159**, **161**. The DCI application **153** is executed by a Java virtual machine **149** to manage the download of Java applets from a network management server (NMS) **170**. A library of Java objects **155** is provided for use by the Java applets **157**, **159**, **161** and the DCI application **153**.

**[0032]** As above, it should be noted that the use of Java is not essential to the present invention and is used for purposes of illustration and explanation. Other programming languages may be used in its place.

**[0033]** In one implementation, the NMS **170** supplies Java applets to the switch **17** in a hyper-text transfer protocol (HTTP) data stream. Other protocols may also be used. The constituent packets of the HTTP data stream are addressed to the IP address of the switch and are directed to the processing unit after being received by the I/O unit coupled to the NMS **170**. After authenticating the HTTP data stream, the DCI application **153** stores the Java applets provided in the data stream in the memory of the processing unit and executes a method to invoke each applet. An applet is invoked by supplying the Java virtual machine **149** with the address of the constructor method of the applet and causing the Java virtual machine **149** to begin execution of the applet code. Program code defining the Java virtual machine **149** is executed to interpret the platform independent byte codes of the Java applets **157**, **159**, **161** into native instructions that can be executed by a processor within the processing unit.

**[0034]** According to one embodiment, the monitor applet **157**, policy enforcement applet **159** and configuration applet **161** communicate with the device management code **147** through a Java-native interface (JNI) **151**. The JNI **151** is essentially an application programming interface (API) and provides a set of methods that can be invoked by the Java applets **157**, **159**, **161** to send messages and receive responses from the device management code **147**. In one implementation, the JNI **151** includes methods by which the monitor applet **157** can request the device management code **147** to gather error information and traffic statistics from the device hardware **141**. The JNI **151** also includes methods by which

the configuration applet **161** can request the device management code **147** to write configuration information to the device hardware **141**. More specifically, the JNI **151** includes a method by which, the configuration applet **161** can indicate that priority queuing should be performed for specified classes of traffic, including, but not limited to, the classes of traffic discussed above in reference to FIG. 4. In this way, a user-coded configuration applet **161** may be executed by the Java virtual machine **149** within the switch **17** to invoke a method in the JNI **151** to request the device management code **147** to write information that assigns selected classes of traffic to be queued in the priority egress queue. In effect, the configuration applet **161** assigns virtual queues defined by the selected classes of traffic to feed into the priority egress queue.

**[0035]** As noted above, although a Java virtual machine **149** and Java applets **157**, **159**, **161** have been described, other virtual machines, interpreters and scripting languages may be used in alternate embodiments. Also, as discussed below, more or fewer Java applets may be used to perform the monitoring, policy enforcement and configuration functions in alternate embodiments.

**[0036]** FIG. 6 illustrates an example of dynamic assignment traffic classes to a priority queue. An exemplary network includes switches A and B coupled together at physical ports **32** and **1**, respectively. Suppose that a network administrator or other user determines that an important server **175** on port **2** of switch A requires a relatively high quality of service (QoS), and that, at least in switch B, the required QoS can be provided by ensuring that at least 20% of the egress capacity of switch B, port **1** is reserved for traffic destined to the MAC address of the server **175**. One way to ensure that 20% egress capacity is reserved to traffic destined for the server **175** is to assign priority queuing for packets destined to the MAC address of the server **175**, but not for other traffic. While such an assignment would ensure priority egress to the server traffic, it also may result in unnecessarily high bandwidth allocation to the server **175**, potentially starving other important traffic or causing other important traffic to become bottlenecked behind less important traffic in the best effort queue. For example, suppose that there are at least two other MAC address destinations, MAC address A and MAC address B, to which the user desires to assign priority queuing, so long as the egress capacity required by the server-directed traffic is available. In that case, it would be desirable to dynamically configure the MAC address A and MAC address B traffic to be queued in either the priority queue or the best effort queue according to existing traffic conditions. In at least one embodiment, this is accomplished using monitor, policy enforcement and configuration applets that have been downloaded to switch B and which are executed in a Java client in switch B as described above in reference to FIG. 5.

**[0037]** FIG. 6 includes exemplary pseudocode listings of monitor, policy enforcement and configuration applets **178**, **179**, **180** that can be used to ensure that at least 20% of the egress capacity of switch B, port **1** is reserved for traffic destined to the server **175**, but without unnecessarily denying priority queuing assignment to traffic destined for MAC addresses A and B. After initialization, the monitor applet **178** repeatedly measures of the port **1** line utilization from the device hardware. In one embodiment, the ARU in the I/O unit that manages port **1** keeps a count of the number of packets destined for particular egress ports, packets destined for particular MAC addresses, packets destined for particular

VLANs, packets that form part of a particular IP flow, packets having a particular IP protocol, and so forth. The ARU also tracks the number of errors associated with these different classes of traffic, the number of packets from each class of traffic that are dropped, and other statistics. By determining the change in these different statistics per unit time, a utilization factor may be generated that represents the percent utilization of the capacity of an egress port, an I/O unit or the overall switch. Error rates and packet drop rates may also be generated.

[0038] In one embodiment, the monitor applet **178** measures line utilization by invoking methods in the JNI to read the port **1** line utilization resulting from traffic destined for MAC address A and for MAC address B on a periodic basis, e.g., every 10 milliseconds.

[0039] The policy enforcement applet **179** includes variables to hold the line utilization percentage of traffic destined for MAC address A (A %), the line utilization percentage of traffic destined for MAC address B (B %), the queue assignment (i.e., priority or best effort) of traffic destined for the server MAC address (QA\_S), the queue assignment of traffic destined for MAC address A (QA\_A) and the queue assignment of traffic destined for MAC address B. Also, a constant, DELTA, is defined to be 5% and the queue assignments for the MAC address A, MAC address B and server MAC address traffic are initially set to the priority queue.

[0040] The policy enforcement applet **179** also includes a forever loop in which the line utilization percentages A % and B % are obtained from the monitor applet **178** and used to determine whether to change the queue assignments QA\_A and QA\_B. If the MAC address A traffic and the MAC address B traffic are both assigned to the priority queue (the initial configuration) and the sum of the line utilization percentages A % and B % exceeds 80%, then less than 20% line utilization remains for the server-directed traffic. In that event, the MAC address A traffic is reassigned from the priority queue to the best effort queue (code statement **181**). If the MAC address A traffic is assigned to the best effort queue and the MAC address B traffic is assigned to the priority queue, then the MAC address A traffic is reassigned to the priority queue if the sum of the line utilization percentages A % and B % drops below 80% less DELTA (code statement **183**). The DELTA parameter provides a deadband to prevent rapid changing of priority queue assignment.

[0041] If the MAC address A traffic is assigned to the best effort queue and the MAC address B traffic is assigned to the priority queue and the line utilization percentage B % exceeds 80%, then less than 20% line utilization remains for the server-directed traffic. Consequently, the MAC address B traffic is reassigned from the priority queue to the best effort queue (code statement **185**). If the MAC address B traffic is assigned to the best effort queue and the line utilization percentage B % drops below 80% less DELTA, then the MAC address B traffic is reassigned to the priority queue (code statement **187**). Although not specifically provided for in the exemplary pseudocode listing of FIG. 6, the policy enforcement applet **179** may treat the traffic destined for the MAC A and MAC B addresses more symmetrically by including additional statements to conditionally assign traffic destined for MAC address A to the priority queue, but not traffic destined for MAC address B. In the exemplary pseudocode listing of FIG. 6, the policy enforcement applet **179** delays for 5 milliseconds at the end of each pass through the forever loop before repeating.

[0042] The configuration applet **180** includes variables, QA\_A and QA\_B, to hold the queue assignments of the traffic destined for the MAC addresses A and B, respectively. Variables LAST\_QA\_A and LAST\_QA\_B are also provided to record the history (i.e., most recent values) of the QA\_A and QA\_B values. The LAST\_QA\_A and LAST\_QA\_B variables are initialized to indicate that traffic destined for the MAC addresses A and B is assigned to the priority queue.

[0043] Like the monitor and policy enforcement applets **178**, **179**, the configuration applet **180** includes a forever loop in which a code sequence is executed followed by a delay, in the exemplary listing of FIG. 6, the first operation performed by the configuration applet **180** within the forever loop is to obtain the queue assignments QA\_A and QA\_B from the policy enforcement applet **179**. If the queue assignment indicated by QA\_A is different from the queue assignment indicated by LAST\_QA\_A, then a JNI method is invoked to request the device code to reconfigure the queue assignment of the traffic destined for MAC address A according to the new QA\_A value. The new QA\_A value is then copied into the LAST\_QA\_A variable so that subsequent queue assignment changes are detected. If the queue assignment indicated by QA\_B is different from the queue assignment indicated by LAST\_QA\_B, then a JNI method is invoked to request the device code to reconfigure the queue assignment of the traffic destined for MAC address B according to the new QA\_B value. The new QA\_B value is then copied into the LAST\_QA\_B variable so that subsequent queue assignment changes are detected. By this operation, and the operation of the monitor and policy enforcement applets **178**, **179**, traffic destined for the MAC addresses A and B is dynamically assigned to the priority queue according to real-time evaluations of the traffic conditions in the switch.

[0044] Although a three-applet implementation is illustrated in FIG. 6, more or fewer applets may be used in an alternate embodiment. For example, the functions of the monitor, policy enforcement and configuration applets **178**, **179**, **180** may be implemented in a single applet. Alternatively, multiple applets may be provided to perform policy enforcement or other functions using different queue assignment criteria. For example, one policy enforcement applet may make priority queue assignments based on destination MAC addresses, while another policy enforcement applet makes priority queue assignments based on error rates or line utilization of higher level protocols. Multiple monitor applets or configuration applets may similarly be provided.

[0045] Although queue assignment policy based on destination MAC address is illustrated in FIG. 6, myriad different queue assignment criteria may be used in other embodiments. For example, instead of monitoring and updating queue assignment based on traffic to destination MAC addresses, queue assignments may be updated on other traffic patterns, including traffic to specified destination ports, traffic from specified source ports, traffic from specified source MAC addresses, traffic that forms part of a specified IP flow, traffic that is transmitted using a specified protocol (e.g., HTTP, FTP or other protocols) and so forth. Also, queue assignments may be updated based on environmental conditions such as time of day, changes in network configuration (e.g., due to failure or congestion at other network nodes), error rates, packet drop rates and so forth. Monitoring, policy enforcement and configuration applets that combine many or all of the above-

described criteria may be implemented to provide sophisticated traffic handling capability in a packet forwarding device.

**[0046]** Although dynamic assignment of traffic classes to a priority egress queue has been emphasized, the methods and apparatuses described herein may alternatively be used to assign traffic classes to a hierarchical set of queues anywhere in a packet forwarding device including, but not limited to, ingress queues and queues associated with delivering and receiving packets from the switching fabric. Further, although the queue assignment of traffic classes has been described in terms of a pair of queues (priority and best effort), additional queues in a prioritization hierarchy may be used without departing from the spirit and scope of the present invention.

**[0047]** Further, although the modification of various queues in this way has been described herein, the invention is not so limited and other embodiments also exist. For example, traffic can be filtered based on its type—source (e.g., source MAC address or source VLAN), ingress port, destination (e.g., destination MAC address or destination IP address), egress port, protocol (e.g., FTP, HTTP) or other hardware-supported filters. In one embodiment, filtering of unicast traffic is determined based on destination parameters such as egress port, destination MAC address or IP address, while filtering of multicast traffic is determined based on source parameters such as ingress port, source MAC address or source IP address.

**[0048]** Filtering may be based on environmental conditions, such as time of day, changes in network configuration (e.g., due to failure or congestion at other network nodes), error rates, packet drop rates, line utilization of higher-level protocols. It may be based on traffic patterns such as traffic from specified source ports, traffic to specified destination ports, traffic from specified source MAC addresses or traffic that forms part of a specified IP flow. Various other hardware counters, monitors and dynamic values can be read from the hardware.

**[0049]** Still further, dynamic filtering decisions may be made on how to process packets other than choosing whether they should go to a priority or best effort queue; for example, they may be dropped or copied, or traffic of a specific type as described above may be diverted. Packet headers may be modified, and use of differentiated services (DS), quality of service (QoS), TOS, TTL, destination and the like is possible as long as it is supported by the hardware. The configurability of filtering and subsequent processing in the invention is, in fact, limited only by the hardware and numerous possibilities for filtering and subsequent processing of traffic other than those described herein will be readily apparent to those skilled in the art after reading and understanding this application.

**[0050]** As an example, consider the routing of multimedia traffic. Such traffic might be sent by three or more separated streams defined by, e.g., virtual port number. This traffic could be filtered and processed to dynamically add or drop specific streams. Based on such dynamic adaptation, active network applications on nodes between the source and destination can negotiate and dynamically set different adaptation mechanisms. As described above, the invention is of course not limited to this example, and in fact is intended to cover such filtering and processing using future hardware platforms which provide new capabilities and which afford new ways of using and controlling such functionality.

**[0051]** In the foregoing specification, the invention has been described with reference to specific exemplary embodiments thereof. It will, however, be evident that various modifications and changes may be made to the specific exemplary embodiments without departing from the broader spirit and scope of the invention as set forth in the appended claims. Accordingly, the specification and drawings are to be regarded in an illustrative rather than a restrictive sense.

1. In a packet forwarding device in a network in which packet flows are assigned respective classes and each respective class is accorded a respective packet forwarding treatment, a method comprising:

detecting a predetermined time of day; and

responsive to detecting the predetermined time of day, changing the respective packet forwarding treatment accorded to at least one class of packet flow from a first packet forwarding treatment to a second packet forwarding treatment.

2. The method of claim 1, wherein changing the respective packet flow treatment accorded to the at least one class of packet flow comprises changing assignment of the at least one class of packet flow from a queue having a first priority to a queue having a second priority.

3. The method of claim 1, wherein changing the respective packet flow treatment accorded to the at least one class of packet flow comprises dropping packets of the at least one class of packet flow.

4. The method of claim 1, wherein changing the respective packet flow treatment accorded to the at least one class of packet flow comprises copying packets of the at least one class of packet flow.

5. The method of claim 1, wherein changing the respective packet flow treatment accorded to the at least one class of packet flow comprises diverting packets of the at least one class of packet flow.

6. The method of claim 1, wherein a packet flow is assigned a respective class based on at least one IP flow parameter of the packet flow.

7. The method of claim 1, wherein a packet flow is assigned a respective class based on a respective source of the packet flow.

8. The method of claim 7, wherein the packet flow is assigned the respective class based on a MAC address of the source of the packet flow.

9. The method of claim 7, wherein the packet flow is assigned the respective class based on a VLAN associated with the source of the packet flow.

10. The method of claim 1, wherein a packet flow is assigned a respective class based on a destination of the packet flow.

11. The method of claim 10, wherein the packet flow is assigned a respective class based on a MAC address of the destination of the packet flow.

12. The method of claim 10, wherein the packet flow is assigned the respective class based on a VLAN associated with the destination of the packet flow.

13. The method of claim 1, wherein the packet flow is assigned a respective class based on an ingress port associated with the packet flow.

14. The method of claim 1, wherein the packet flow is assigned a respective class based on an egress port associated with the packet flow.

15. The method of claim 1, wherein the packet flow is assigned a respective class based on a virtual port associated with the packet flow.

16. The method of claim 1, wherein a packet flow is assigned a respective class based on a protocol of the packet flow.

17. The method of claim 16, wherein a packet flow is assigned a respective class based on whether is associated with a specified high level protocol.

18. The method of claim 17, wherein a packet flow is assigned a respective class if it is associated with an FTP flow.

19. The method of claim 17, wherein the packet flow is assigned a respective class if it is associated with an HTTP flow.

20. The method of claim 1, wherein a packet flow is assigned a respective class based on a traffic type of the of the packet flow.

21. The method of claim 1, wherein a packet flow is assigned a respective class based on whether it is associated with a specified IP flow.

22. A non-transitory, processor-readable medium carrying instructions for execution by at least one processor, the instructions comprising instructions executable in a packet forwarding device in a network in which packet flows are assigned respective classes and each respective class is accorded a respective packet forwarding treatment, the instructions comprising:

instructions executable to detect a predetermined time of day; and

instructions executable responsive to detecting the predetermined time of day, to change the respective packet forwarding treatment accorded to at least one class of packet flow from a first packet forwarding treatment to a second packet forwarding treatment.

23. The medium of claim 22, wherein the instructions executable to change the respective packet flow treatment accorded to the at least one class of packet flow comprise instructions executable to change assignment of the at least one class of packet flow from a queue having a first priority to a queue having a second priority.

24. The medium of claim 22, wherein the instructions executable to change the respective packet flow treatment accorded to the at least one class of packet flow comprise instructions executable to drop packets of the at least one class of packet flow.

25. The medium of claim 22, wherein the instructions executable to change the respective packet flow treatment accorded to the at least one class of packet flow comprise instructions executable to copy packets of the at least one class of packet flow.

26. The medium of claim 22, wherein the instructions executable to change the respective packet flow treatment accorded to the at least one class of packet flow comprise instructions executable to divert packets of the at least one class of packet flow.

27. The medium of claim 22, wherein the instructions comprise instructions executable to assign a packet flow a respective class based on at least one IP flow parameter of the packet flow.

28. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a respective source of the packet flow.

29. The medium of claim 28, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a MAC address of the source of the packet flow.

30. The medium of claim 28, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a VLAN associated with the source of the packet flow.

31. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a destination of the packet flow.

32. The medium of claim 31, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a MAC address of the destination of the packet flow.

33. The medium of claim 31, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a VLAN associated with the destination of the packet flow.

34. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on an ingress port associated with the packet flow.

35. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on an egress port associated with the packet flow.

36. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a virtual port associated with the packet flow.

37. The medium of claim 22, wherein the instructions comprise instructions executable to assign a respective class to a packet flow based on a protocol of the packet flow.

38. The medium of claim 37, wherein a packet flow is assigned a respective class based on whether is associated with a specified high level protocol.

39. The medium of claim 38, wherein the instructions executable to assign a respective class to the packet flow based on the protocol of the packet flow comprise instructions executable to assign the packet flow the respective class if it is associated with an FTP flow.

40. The medium of claim 38, wherein the instructions executable to assign a respective class to the packet flow based on the protocol of the packet flow comprise instructions executable to assign the packet flow the respective class if it is associated with an HTTP flow.

41. The medium of claim 22, comprising instructions executable to assign a packet flow a respective class based on a traffic type of the of the packet flow.

42. The medium of claim 22, wherein a packet flow is assigned a respective class based on whether it is associated with a specified IP flow.
